

ABSTRACT

An arm protection apparatus for a patient's arms when the patient is in a prone or supine position. An injured party who is unable to voice complaints of pain or pressure may be positioned on an operating table or on a stretcher. The patient may be unconscious. There is a risk of injury to a patient's arm unless the patient's arm is secured in a safe position and cushioned from outside pressure. The arm protection apparatus involves a central pad, which is positioned under a patient's body. Sections come off the central pad, which may be positioned around a patient's arm. Ordinarily, a patient's upper arm and lower arm will both be contained within separate sections that are attached to the central portion of the pad. The pad will be constructed of a soft foam-like material, which is radiolucent and easily folded or cut as need be. The pad will ordinarily be disposable and discarded after one use and can be packaged and stored in a sterile container.
